Hair Transplantation

Hair Transplantation is a surgical procedure used to address hair loss or baldness. It involves moving hair follicles from a part of the body where hair is plentiful (the donor area) to a part where hair is lacking (the recipient area). The process typically involves several steps:

1. **Donor Area** - This is the area of the body where the hair is taken from. This is usually the back of the scalp, where hair growth is densest.
2. **Graft Preparation** - The hair follicles are then carefully removed from the donor area and placed in a way that they will grow in the new location. This can be done in a few different ways:
   - **Follicular Unit Transplantation (FUT)**: This involves the removal of linear strips of donor tissue, which are then dissected into individual follicular units.
   - **Follicular Unit Extraction (FUE)**: This is a more modern technique where individual hair follicles are removed with a small punch biopsy tool, offering less scarring.
3. **Recipient Area** - The area where the transplanted hair will be placed. This is typically the bald or thinning part of the scalp.
4. **Recovery** - The transplanted hair usually grows at about the same rate as it did in the donor area, and the results can last a lifetime.

Hair Transplantation is often used to treat conditions such as androgenetic alopecia (male pattern baldness), which affects around 70% of men at some point in their lives. It can also be used to treat women with hair loss associated with medical conditions or certain types of hair loss that are not caused by genetics.

The success of hair transplant surgery depends on the type of procedure, the individual’s hair density, and the skill of the surgeon. Results can vary, and some degree of hair loss is normal as the body continues to age.
